데이터과학

L09.1: Clustering Practice

Kookmin University

목차

- k-means 구현
- 이미지 처리 응용
- k-means using sklearn

모듈 불러오기

• 사용할 모듈 import 하기

```
import random
import numpy as np
import matplotlib.pyplot as plt
```

K-Means

```
def kmeans(k, points):
  prev assignment = []
  # 1. 임의로 k개의 점을 중심점으로 선택 (forgy)
  centroids = points[np.random.choice(points.shape[0], replace=False, size=k)]
  for epoch in range(10):
      # 2. 각 점이 할당될 중심점을 계산
      assignments = [assign(p, centroids, k) for p in points]
      # 3. 새로운 centroid 계산
      centroids = compute centroids(assignments, points, k)
      # 4. 클러스터에 변화가 없을 경우 종료
      if prev assignment == assignment:
          break
      prev assignment = assignment
  return assignments, centroids
```

assign()

```
def assign(point, centroids, k):
    return min(range(k), key=lambda i: np.dot(centroids[i]-point, centroids[i]-point))
```

compute_centroids()

```
def compute_centroids(assignments, points, k):
    vec_sum = [np.zeros(len(points[0])) for _ in range(k)]
    counts = [0] * k

    for i, p in zip(assignments, points):
        vec_sum[i] += p
        counts[i] += 1

    return [vec_sum[i]/counts[i] if counts[i] > 0 else random.choice(points) for i in range(k)]
```

테스트

```
# 데이터 생성
k = 3

points1 = np.random.randn(80, k)

points2 = np.random.randn(20, k) + np.array([5, 5, 5])

points3 = np.random.randn(20, k) + np.array([10, 5, 0])

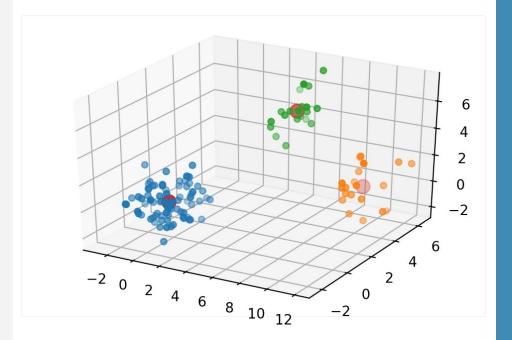

points = np.concatenate( (points1, points2, points3) )

# kmeans 실행

assignments, centroids = kmeans(k, points)
```

테스트

```
# 결과 확인
fig = plt.figure()
ax = fig.gca(projection='3d')
clusters = [[] for _ in range(k)]
for a, p in zip(assignments, points):
   clusters[a].append(p)
for cluster in clusters:
   ax.scatter(*zip(*cluster))
ax.scatter(*zip(*centroids), s=100)
plt.show()
```

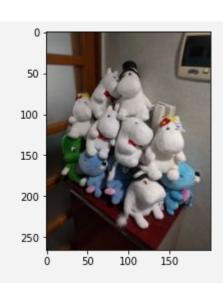

목차

- k-means 구현
- 이미지 처리 응용
- k-means using sklearn

사진 불러오기

```
from PIL import Image
# 사진 불러오기 & 크기 조절 & 화면에 출력
im = Image.open("IMG_20171130_110254.jpg")
width = 200
height = im.height * width // im.width
im = im.resize((width, height))
plt.imshow(im)
plt.show()
```

k-means 적용, 결과 확인

```
# 데이터 준비 & k-means 알고리즘 적용
pixels = np.array(im).reshape(-1,3)
assignments, centroids= kmeans(10, pixels)
                                                              100
# 모든 픽셀의 색을 centroid중 하나로 선택
                                                              150
for a, i in zip(assignments, range(pixels.shape[0])):
                                                               200
   pixels[i] = centroids[a]
                                                               250
# 바뀐 그림 출력
im remastered = Image.fromarray(pixels.reshape(im.height, im.width, 3), 'RGB')
plt.imshow(im remastered)
plt.show()
```

목차

- k-means 구현
- 이미지 처리 응용
- k-means using sklearn

k-means using sklearn

- label_: 각점이 할당된 cluster 번호
- cluster_centers_: cluster별 중심 점 좌표

```
from sklearn.cluster import KMeans
...
kmeans = KMeans(n_clusters=10)
kmeans.fit(pixels)

for a, i in zip(kmeans.labels_, range(pixels.shape[0])):
    pixels[i] = kmeans.cluster_centers_[a]
...
```
